Mis- or under diagnosis of MPM still a problem today

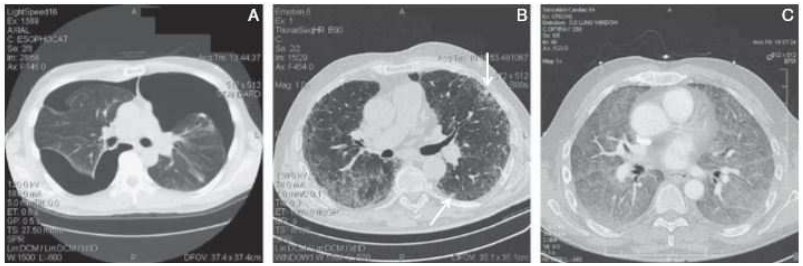
Pleural mesothelioma is a rare cancer <0.3% of all cancers (Francim Registry Network)

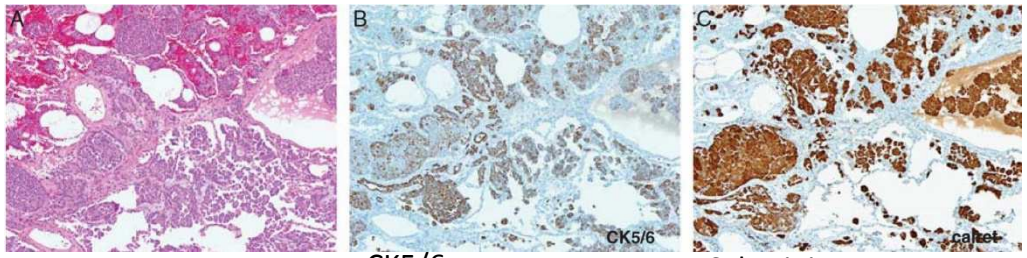
1) Mesothelioma is an heterogeneous cancer a great mimickers of other malignancies that metastazise to the pleura

2) The separation between benign lesions and malignant pleural mesothelioma is morphologically challenging

Clinically

1° Diffuse Intrapulmonary Malignant Mesothelioma Masquerading as Interstitial Lung Disease A Distinctive Variant of Mesothelioma

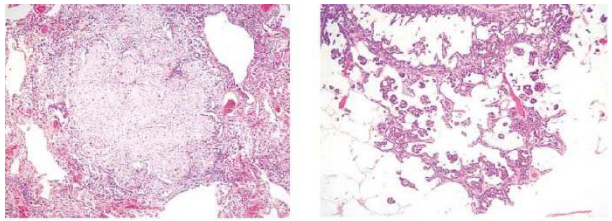




CK5/6 Calretinin

Larsen B et al, Am J Surg Pathol 2013;37:1555–1564

2° Intraparenchymal growth with lepidic carcinoma like pattern…. Nind et al, Histopathology 2003 vol 42 issue 2.150-55

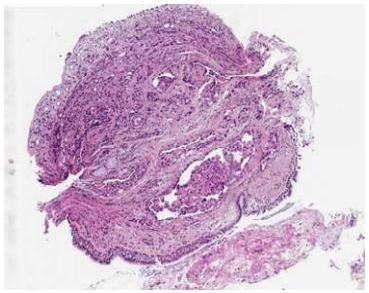


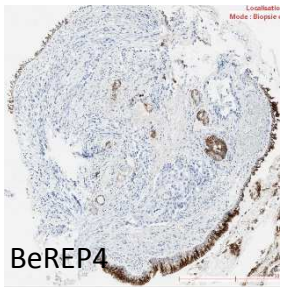
- 3° Bone marrow metastasis of MPM Ihari et al Intern Med 2018 or Brain metastasis revealing a localized MPM Ertan G, et al. BMJ Case Rep 2016. doi:10.1136/bcr-2016-21734

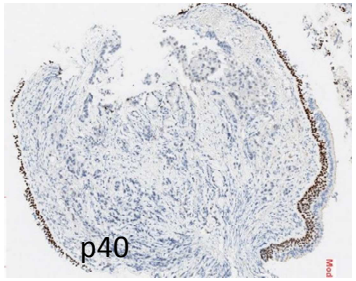
4° Malignant mesothelioma mimicking rheumatoid pleurisy. Nanke et al, J Clin Oncol. 2001 Sep 1;19(17):3782-4.

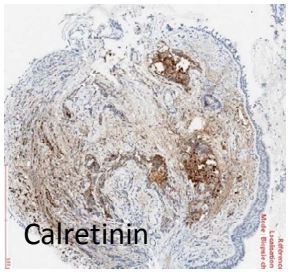
Small biopsies and unusual location

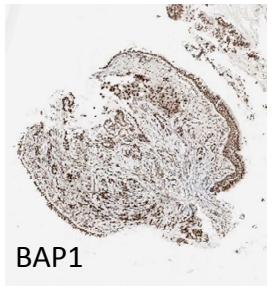
Male 83 years old with a pleural tumor on CT scan



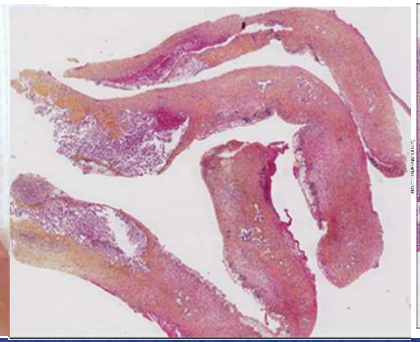


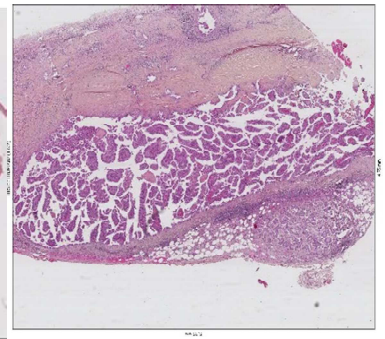






- Female 75 yrs, smoker, workers in the mills
- Diminution of general health and loss of weight
- Unilateral pleural effusion
- Went to hospital for thoracoscopy
- CT scan hilar mass
- Surgical evaluation showed contained pleural effusion
- Multiples biopsies.





Cagle et al, concurrent mesothelioma and Adenocarcinoma Mod Pathol 1993

Pathologically the major causes of misdiagnosis are:

- Metastasis
  - EMM versus carcinoma metastasis lung and breast & renal, ovarian
- SMM versus Sarcomatoid carcinoma , versus primitive sarcoma of the pleura
- Mesothelioma versus other tumors of mesothelial origin

The major causes of underdiagnosis are:

- Benign/reactive lesions versus mesothelioma or question of sampling

Nicholson A et al , Accepted JTO

towards a more multidisciplinary approach, Nicholson et al, JTO in press

1) **Classification should include: Architectural patterns, Stromal response, Cytologic characteristics for prognostication**
2) **Malignant mesothelioma in situ could be an additional category**
3) **Favorable/unfavorable category should be routinely recognized and reported**
4) **Clinically relevant molecular abnormalities BAP1, CDKN2A (p16) HD, PDL-1 should also be incorporated in the reports**
5) **Other molecular data should be accrued as part of future clinical trials (MET etc..)**
6) Resection specimens (Pleurectomy/decortication and EPP) should be pathologically staged while small biopsies should be clinically staged
7) 3 different areas should be samples if possible
8) Correlation with image –acquisition protocol/imaging terminology are needing standardization for clinical staging and research practice
9) **Multidisciplinary board should include pathologists to ensure appropriate treatment**
10) **All histologic subtypes should be considered for chemotherapy**
11) **Patients with Biphasic and sarcomatoid mesothelioma should not be excluded from first line clinical trials**
12) **Tumor subtyping should be assessed in relation to response to immunotherapy**
13) Systematic screening of all patients for germline mutation is not recommended in the absence of family history of BAP1 syndrom

Original contribution

The differential diagnosis between pleural sarcomatoid mesothelioma and spindle cell/pleomorphic (sarcomatoid) carcinomas of the lung: evidence-based guidelines from the International Mesothelioma Panel and the MESOPATH National Reference Center☆

Alberto M. Marchevsky MD[a,*], Nolwenn LeStang[b], Kenzo Hiroshima MD[c], Giuseppe Pelosi MD[d], Richard Attanoos MD[e], Andrew Churg MD[f], Lucian Chirieac MD[g], Sanja Dacic MD[h], Aliya Husain MD[i], Andras Khoor MD[j], Sonja Klebe MD[k], Silvie Lantuejoul MD[l], Victor Roggli MD[m], Jean-Michel Vignaud MD[n], Birgit Weynard MD[o], Jennifer Sauter MD[p], Douglas Henderson MD[k], Kasuzi Nabeshima MD[q], Francoise Galateau-Salle MD[b]

The study was designed to review the experience at MESOPATH and query the English literature for best available evidence for the immunophenotype of SMM and SPC

Table 1 Demographics of patients diagnosed with sarcomatoid malignant mesothelioma and spindle cell/pleomorphic carcinoma at MESOPATH from 1998 to 2016

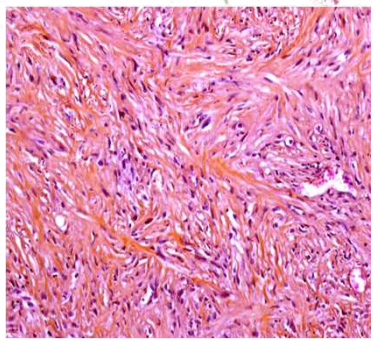
Sarcomatoid mesothelioma versus Sarcomatoid Carcinoma

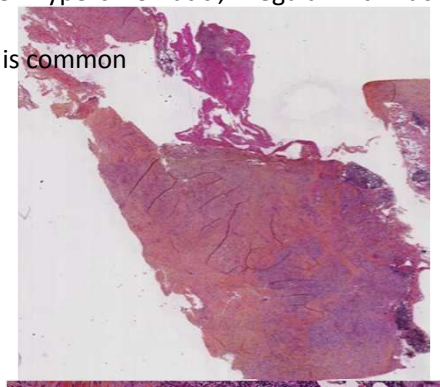
WHO 2015 9051/3 ICD-O code

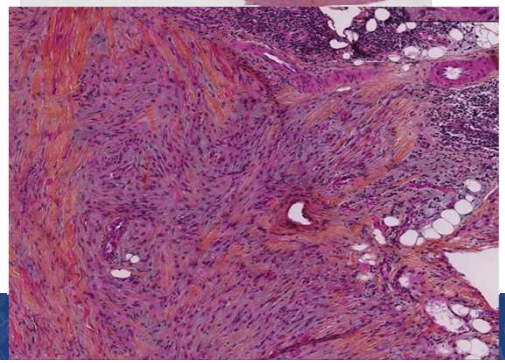
Proliferation of spindle cells arranged in fascicles or with haphazard pattern involving the adipose tissue or lung parenchyma and may present heterologous elements.
Wide range of morphologies but in conventional SM
Nuclear atypia varies from minimal to moderate



WHO 2015 8022/3 ICD-O code

Malignant spindle cell proliferation arranged in fascicular or storiform patterns.
Differentiated elements are absent
Nuclei are often hyperchromatic , irregular with nucleoli and granular chromatin
Inflammation is common





Can we use BAP1 immunostaining for the separation between SMM vs SC.No

NO!!!

Righi et al, JTO 2016 **Loss of BAP1 nuclear staining is rare in SMM and more prevalent in EMM**

SC

Can we use GATA3 for the separation between SM and SC: Yes

- GATA binding protein 3 (GATA3) is a transcription factor,
- GATA3 function is important in the regulation of genes such as MUC1/EMA involved in the luminal differentiation of breast epithelium and genes related to T-cell development

- GATA3 cl.L50-823 has been evaluated in surgical pathology as a marker for breast metastatic carcinoma in 80-90% and 67% of triple neg tumors

Berg & Churg(Am J Surg Pathol 2017;41:1221–1225)

TABLE 1. GATA3 Diffuseness, Intensity, and Total Score

Diffuseness Score	Sarcomatoid Mesotheliomas (N = 19) (n [%])	Sarcomatoid Carcinomas (N = 13) (n [%])	Intensity Score	Sarcomatoid Mesotheliomas (N = 19) (n [%])	Sarcomatoid Carcinomas (N = 13) (n [%])

Deep learning-based classification of mesothelioma improves prediction of patient outcome

Pierre Courtiol[1,8], Charles Maussion[1,8], Matahi Moarii[1], Elodie Pronier[1], Samuel Pilcer[1], Meriem Sefta[1], Pierre Manceron[1], Sylvain Toldo[1], Mikhail Zaslavskiy[1], Nolwenn Le Stang[2], Nicolas Girard[3,4], Olivier Elemento[5], Andrew G. Nicholson[6], Jean-Yves Blay[7], Françoise Galateau-Sallé[2,8], Gilles Wainrib[1,8] and Thomas Clozel[1,8]*

Malignant mesothelioma (MM) is an aggressive cancer primarily diagnosed on the basis of histological criteria[1]. The 2015 World Health Organization classification subdivides mesothelioma tumors into three histological types: epithelioid, biphasic and sarcomatoid MM. MM is a highly complex and heterogeneous disease, rendering its diagnosis and histological typing difficult and leading to suboptimal patient care and decisions regarding treatment modalities[2]. Here we have developed a new approach—based on deep convolutional neural networks—called MesoNet to accurately predict the overall survival of mesothelioma patients from whole-slide digitized images, without any pathologist-provided locally annotated regions. We validated MesoNet on both an internal validation cohort from the French MESOBANK and an independent cohort from The Cancer Genome Atlas (TCGA). We also demonstrated that the model was more accurate in predicting patient survival than using current pathology practices. Furthermore, unlike classical black-box deep learning methods, MesoNet identified regions contributing to patient outcome prediction. Strikingly, we found that these regions are mainly located in the stroma and are histological features associated with inflammation, cellular diversity and vacuolization. These findings suggest that deep learning models can identify new features predictive of patient survival and potentially lead to new biomarker discoveries.

16 months), whereas SMM patients have the worst prognosis (OS of 5 months) and BMM patients have an intermediate prognosis[6]. This histological classification is of prognostic and therapeutic value[7,8] but is insufficient to cover the extreme variability in clinical features and patient outcomes in MM patients. This highlights the important need for developing new methods to identify predictive biomarkers consistently associated with survival[2,9–12].

The advent of deep learning and the availability of thousands of histology slides provides a new opportunity to revisit classical approaches to diagnosis and predicting patient outcomes[12–21]. However, this approach is usually seen as a black-box, where image features contributing to the prediction are hardly intelligible. To address these limitations, we developed MesoNet, a deep learning algorithm specifically customized to analyze large images, such as whole-slide images (WSIs), without any local annotation by pathologists[22].

To build MesoNet, we adapted a recently described algorithm specifically designed to address this scenario[22]. To create prediction models, our algorithm trains deep learning networks from WSIs[22,24] with only global data labels (Extended Fig. 1). First, WSIs from MM patients were preprocessed and divided into small 112×112 µm squares (224×224 pixels), called 'tiles'. These tiles were fed into the network architecture, which assigned a 'survival score' to each tile, through an iterative learning process. Finally, the network selected the tiles of each WSI that were the most relevant to the prediction and used this limited number of tiles to predict patient OS (for a

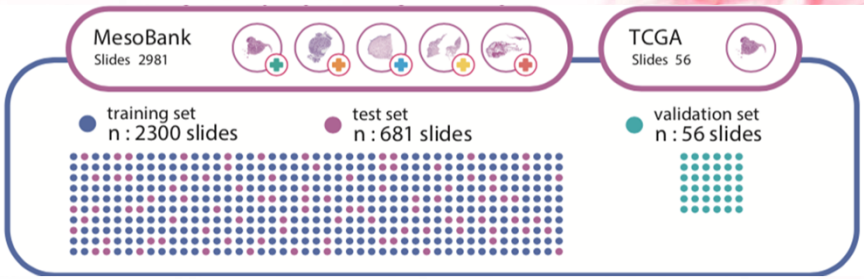
Procédure de certification diagnostique standardisée pour chaque cas enregistré

GOLD STANDARD

Procédure de validation croisée entre les équipes internationales

Data

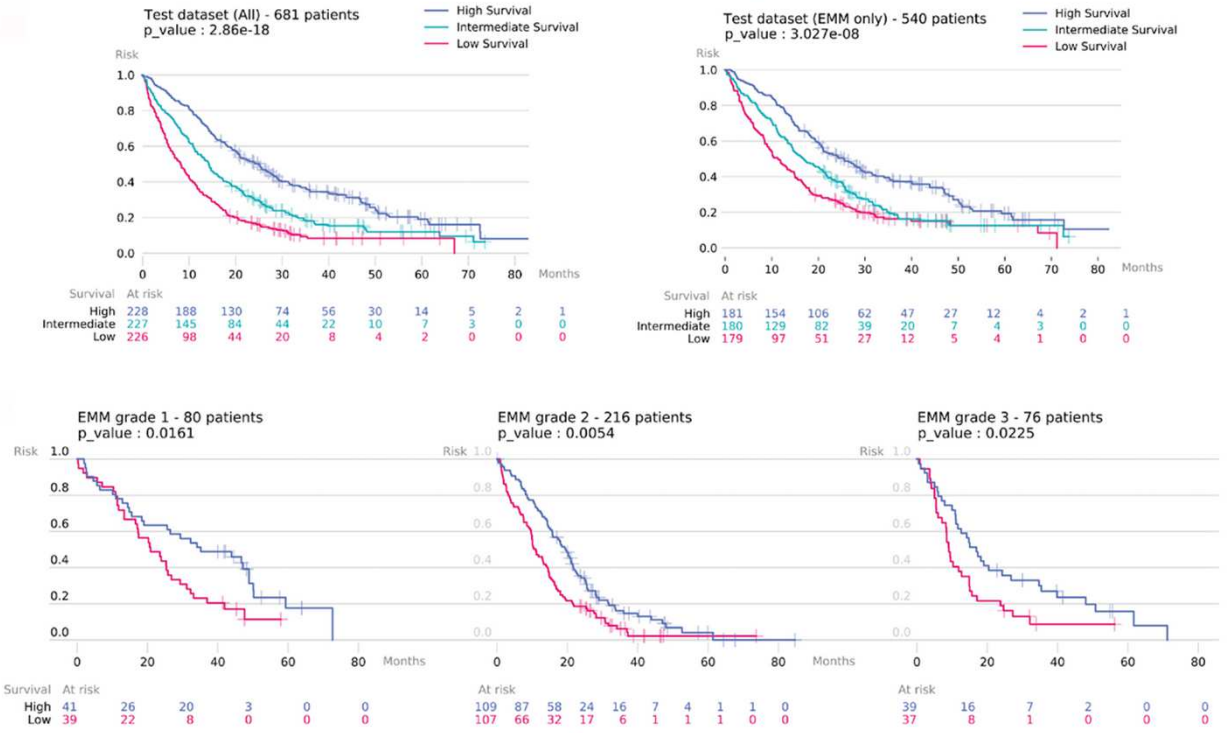
- The MESOPATH / MESOBANK database is an exhaustive repository of French clinical data and HES histological samples pertaining to mesothelioma.
- This dataset was randomly divided into a training set (2,300 slides) and an entirely separate test set (681 slides).
- On the training set, a five-fold cross-validation strategy was applied. The model was then trained on the entire 2,300 training slides and evaluated on the test set of 681 slides.
- Moreover, a validation set of 56 H&E WSIs from 56 MM patients from an independent dataset was obtained from TCGA in order to test MesoNet robustness.



P.Courtiol OWKIN et al,

Results

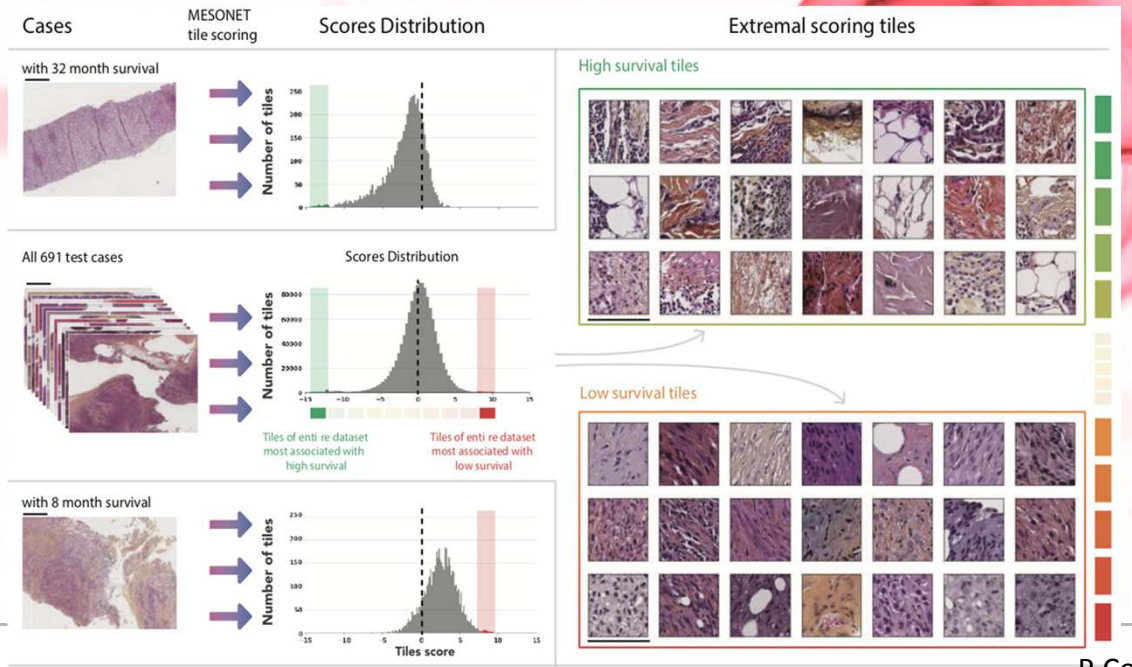
- The model **is able to stratify patients** even within established histological classification



P.Courtiol OWKIN et al,

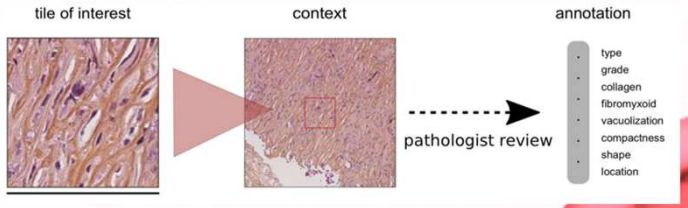
Interpretability

- One can extract the **most predictive tiles** for the algorithm so they can be **analyzed by an expert pathologist**
- The most predictive tiles associated with low survival (n= 50) were located primarily in **stromal regions.**



P.Courtiol OWKIN et al,

Interpretability



- Two independent expert pathologists analyzed the specific histological features differentiating predictive and non-predictive tiles for low and high survival tiles, separately.
- Predictive high survival tiles were of lower-grade tumors, less pleomorphic and showed a greater inflammatory response
- Low survival tiles were of higher-grade tumors, more pleomorphic, atypical and showing a lower inflammatory response

High pleomorphism, atypia and a lower inflammatory response are consistently associated with a lower survival and should be taken into account by pathologists for MM diagnosis and staging.

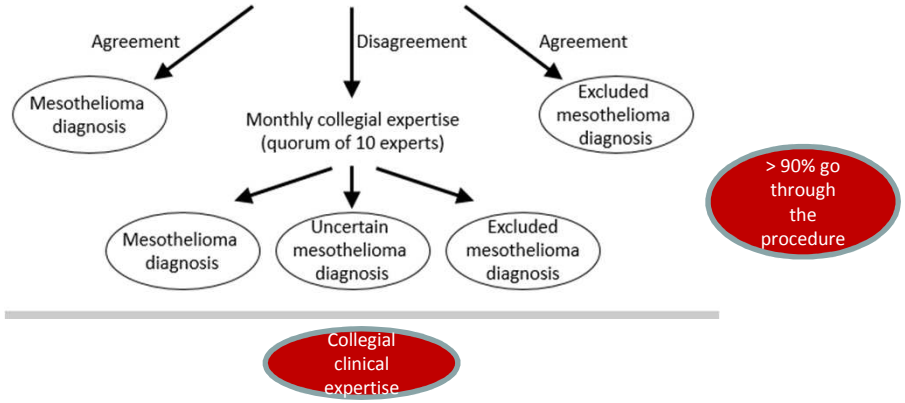
ing

Initial pathologist diagnosis

↓

3 experts blindly reviewed the slides (WHO classification 2015)
Additional IHC (CKs +2 +ve and 2 - ve markers) + specific organ markers (10markers/per case)
since 2012 additional molecular markers BAP1 and FISH CDKNp16 and RNASeq when necessary



Mis and underdiagnosis of MPM is still a problem today need ancillary techniques and knowledge of new entities

An awareness of the clinical settings and diverse morphological, cytological features and stromal characteristics of mesothelioma is important to avoid misdiagnosis.

Immunohistochemistry is still mandatory in the identification of misleading patterns

Molecular markers are crucial tools for the separation of benign versus malignant mesothelial proliferations and RNAseq for a more accurate classification and avoid misdiagnosis.
